Section B

1	(a)	Batches	Units	Price per unit \$	Total revenue \$	Variable cost per unit \$	Total variable costs \$	Fixed costs \$	Total cost \$	Profit \$
		1	1,000	20	20,000	10.00	10,000	10,000	20,000	0
		2	2,000	18	36,000	8.80	17,600	10,000	27,600	8,400
		3	3,000	16	48,000	7.80	23,400	12,000	35,400	12,600
		4	4,000	13	52,000	6.40	25,600	12,000	37,600	14,400
		5	5,000	12	60,000	6.40	32,000	14,000	46,000	14,000

Therefore Jewel Co should import and sell four batches (4,000 units) of headphones since at this point it will make the greatest profit: \$14,400 for the month.

- (b) The algebraic model requires several assumptions to be true. First, there must be a consistent relationship between price (P) and demand (Q), so that a demand equation can be established, usually in the form $P = a - bQ$. Here, although there is a clear relationship between the two, it is not a perfectly linear relationship and so more complicated techniques are required to calculate the demand equation. It also cannot be assumed that a linear relationship will hold for all values of P and Q other than the five given.

Similarly, there must be a clear relationship between demand and marginal cost, usually satisfied by constant variable cost per unit and constant fixed costs. The changing variable costs per unit again complicate the issue, but it is the changes in fixed costs which make the algebraic method less useful in Jewel's case.

The algebraic model is only suitable for companies operating in a monopoly and it is not clear here whether this is the case, but it seems unlikely, so any 'optimum' price might become irrelevant if Jewel's competitors charge significantly lower prices.

Other more general factors not considered by the algebraic model are political factors which might affect imports, social factors which may affect customer tastes and economic factors which may affect exchange rates or customer spending power. The reliability of the estimates themselves – for sales prices, variable costs and fixed costs – could also be called into question.

- 2 (a) The breakeven sales revenue for Swim Co is \$90,000. The company's profit, to the nearest \$10,000, if 500 athletes attend the course is \$20,000 (\$140,000 – \$120,000). (From the graph, it is clear that the precise amount will be nearer \$17,000, i.e. \$140,000 – approximately \$123,000.)

(b) Cost structure

From the chart, it is clear that Line C represents fixed costs, Line B represents total costs and Line A represents total revenue.

Line C shows that initially, fixed costs are \$20,000 even if no athletes attend the course. This level of fixed costs remains the same if 100 athletes attend but once the number of attendees increases above this level, fixed costs increase to \$40,000.

Line B represents total costs. If 100 athletes attend, total costs are \$40,000 (\$400 per athlete). Since \$20,000 of this relates to fixed costs, the variable cost per athlete must be \$200. When fixed costs step up beyond this point at the level of 200 athletes, total costs obviously increase as well and Line B consequently gets much steeper. However, since there are now 200 athletes to absorb the fixed costs, the cost per athlete remains the same at \$400 per athlete (\$80,000/200), even though fixed costs have doubled.

If 300 athletes attend the course, total cost per athlete becomes \$300 each (\$90,000/300). Since fixed costs account for \$40,000 of this total cost, variable costs total \$50,000, i.e. \$166.67 per athlete. So, economies of scale arise at this level, as demonstrated by the fact that Line B becomes flatter.

At 400 athletes, the gradient of the total costs line is unchanged from 300 athletes which indicates that the variable costs have remained the same. There is no further change at 500 athletes; fixed and variable costs remain steady.

Revenue structure

As regards the revenue structure, it can be seen from Line A that for 100–400 athletes the price remains the same at \$300 per athlete. However, if 500 athletes attend, the price has been reduced as the total revenue line becomes flatter. \$140,000/500 means that the price has gone down to \$280 per athlete. This was obviously necessary to increase the number of attendees and at this point, profit is maximised.

3 Total sales revenue = (280,000 x \$55) + (420,000 x \$45) = \$15.4m + 18.9m = \$34.3m.

	\$'000
<i>Less costs:</i>	
Development and design costs	5,600
Patent application costs (including \$20k)	500
Patent renewal costs – 2 years	400
Opportunity cost – ignore	–
Total material costs [(280,000 x \$16) + (420,000 x \$14)]	10,360
Total labour costs [(280,000 x \$8) + (420,000 x \$7)]	5,180
Fixed production overheads	3,800
Marketing costs (working 1)	4,680
Selling and distribution costs	1,500
Environmental costs	250
Total life cycle costs	32,270

Expected profit = \$2.03m

Note

The expected profit has been calculated using life cycle costing not relevant costing. Hence, the \$20,000 salary cost included in patent costs should be included in the life cycle cost. Similarly, the opportunity cost of \$800,000 is not included using life cycle costing whereas if relevant costing was being used to decide on a particular course of action, the opportunity cost would be included.

Working 1

Expected marketing cost in year 1: (0.2 x \$2.2m) + (0.5 x \$2.6m) + (0.3 x \$2.9m) = \$2.61m

Expected marketing cost year 2: (0.3 x \$1.8m) + (0.4 x \$2.1m) + (0.3 x \$2.3m) = \$2.07m

Total expected marketing cost = \$4.68m

4 (a) Maximising group profit

Division L has enough capacity to supply both Division M and its external customers with component L.

Therefore, incremental cost of Division M buying externally is as follows:

Cost per unit of component L when bought from external supplier: \$37

Cost per unit for Division L of making component L: \$20.

Therefore incremental cost to group of each unit of component L being bought in by Division M rather than transferred internally: \$17 (\$37 – 20).

From the group's point of view, the most profitable course of action is therefore that all 120,000 units of component L should be transferred internally.

(b) Calculating total group profit

Total group profits will be as follows:

Division L:

Contribution earned per transferred component = \$40 – \$20 = \$20

Profit earned per component sold externally = \$40 – \$24 = \$16

	\$
120,000 x \$20	2,400,000
160,000 x \$16	2,560,000
	4,960,000
<i>Less fixed costs</i>	(500,000)
Profit	4,460,000

Division M:

Profit earned per component sold externally = \$27 – \$1 = \$26

	\$
120,000 x \$26	3,120,000
<i>Less fixed costs</i>	(200,000)
Profit	2,920,000
Total profit	7,380,000

(c) Problems with current transfer price and suggested alternative

The problem is that the current transfer price of \$40 per unit is now too high. Whilst this has not been a problem before since external suppliers were charging \$42 per unit, it is a problem now that Division M has been offered component L for \$37 per unit. If Division M now acts in its own interests rather than the interests of the group as a whole, it will buy component L from the external supplier rather than from Division L. This will mean that the profits of the group will fall substantially and Division L will have significant unused capacity.

Consequently, Division L needs to reduce its price. The current price does not reflect the fact that there are no selling and distribution costs associated with transferring internally, i.e. the cost of selling internally is \$4 less for Division L than selling externally. So, it could reduce the price to \$36 and still make the same profit on these sales as on its external sales. This would therefore be the suggested transfer price so that Division M is still saving \$1 per unit compared to the external price. A transfer price of \$37 would also presumably be acceptable to Division M since this is the same as the external supplier is offering.

5 (a) Basic variances

Labour rate variance

Standard cost of labour per hour = $\$42/3 = \14 per hour.

Labour rate variance = (actual hours paid x actual rate) – (actual hours paid x std rate)

Actual hours paid x actual rate = \$531,930.

Actual hours paid x std rate = $37,000 \times \$14 = \$518,000$.

Therefore rate variance = $\$531,930 - \$518,000 = \$13,930$ A

Labour efficiency variance

Labour efficiency variance = (actual production in std hours – actual hours worked) x std rate

$[(12,600 \times 3) - 37,000] \times \$14 = \$11,200$ F

(b) Planning and operational variances

Labour rate planning variance

(Revised rate – std rate) x actual hours paid = $[\$14.00 - (\$14.00 \times 1.02)] \times 37,000 = \$10,360$ A.

Labour rate operational variance

Revised rate x actual hours paid = $\$14.28 \times 37,000 = \$528,360$.

Actual cost = \$531,930.

Variance = \$3,570 A.

Labour efficiency planning variance

(Standard hours for actual production – revised hours for actual production) x std rate

Revised hours for each pair of gloves = 3.25 hours.

$[37,800 - (12,600 \times 3.25)] \times \$14 = \$44,100$ A.

Labour efficiency operational variance

(Revised hours for actual production – actual hours for actual production) x std rate

$(40,950 - 37,000) \times \$14 = \$55,300$ F.

(c) Analysis of performance

At a first glance, performance looks mixed because the total labour rate variance is adverse and the total labour efficiency variance is favourable. However, the operational and planning variances provide a lot more detail on how these variances have occurred.

The production manager should only be held accountable for variances which he can control. This means that he should only be held accountable for the operational variances. When these operational variances are looked at it can be seen that the labour rate operational variance is \$3,570 A. This means that the production manager did have to pay for some overtime in order to meet demand but the majority of the total labour rate variance is driven by the failure to update the standard for the pay rise that was applied at the start of the last quarter. The overtime rate would also have been impacted by that pay increase.

Then, when the labour efficiency operational variance is looked at, it is actually \$55,300 F. This shows that the production manager has managed his department well with workers completing production more quickly than would have been expected when the new design change is taken into account. The total operating variances are therefore \$51,730 F and so overall performance is good.

The adverse planning variances of \$10,360 and \$44,100 do not reflect on the performance of the production manager and can therefore be ignored here.
